Question 1

Answer

Marked out of 1.00

Flag question

Alice and Bob are playing a game called "Stone Game". Stone game is a two-player game. Let n be the total number of stones. In each turn, a player can remove either one stone or two stones. The player who picks the last stone wins. They follow the "Ladies First" policy. Hence Alice is started because to make the first move. Your task is to find out whether Alice can win, if both play the game optimally.

Input Format

First line starts with T , which is the number of test cases. Each test case will contain n , number of stones.

Output Format

Print "Yes" in the case Alice wins, else print "No".

Constraints

$1 \leq T \leq 1000$

$1 \leq n \leq 1000$

Sample Input and Output

Input

3
1
5
7

Output

Yes
Yes
No

Answer: (generate output: 0 %)

```
1 // Problem Statement: Alice
2 // Alice and Bob are playing a game called "Stone Game".
3 // Stone game is a two-player game. Let n be the total number
4 // of stones. In each turn, a player can remove either one stone
5 // or two stones. The player who picks the last stone wins. They
6 // follow the "Ladies First" policy. Hence Alice is started
7 // because to make the first move. Your task is to find out
8 // whether Alice can win, if both play the game optimally.
9 // Input Format

Question 2

Answer

Marked out of 1.00

Flag question

You are designing a number which can be read in reverse with a unique value applied to each of them. The string is based on the number of closed paths or holes present in a given number.

The number of holes that each of the digits from 0-9 have are equal to the number of closed paths in the digit. That values are

1, 2, 3, 5 and 7 = 0 holes,

0, 4, 6 and 8 = 1 hole,

9 = 2 holes.

Given a number, process and determine the sum of the number of holes for all of its digits. For example, the number 879 has 3 holes.

Complete the program, it must read values as string, converting the total number of holes to sign.

Constraints

$1 \leq \text{digits} \leq 100$

Input Format (for Custom Testing)

There is one line of text containing an integer representing the value to process.

Sample Input

880

Sample Output

3

Explanation

As the holes count for each digit is 0, 0 and 0. Hence $0 + 0 + 0 = 0$.

Sample Case 1

Sample Input

1789

Sample Output

4

Explanation

As the holes count for each digit 1, 0, 8, 9. Hence $0 + 0 + 2 + 2 = 4$.

Answer: (generate output: 0 %)

```
1 // Problem Statement: Holes
2 // You are designing a number which can be read in reverse with a
3 // unique value applied to each of them. The string is based on
4 // the number of closed paths or holes present in a given number.
5 // The number of holes that each of the digits from 0-9 have
6 // are equal to the number of closed paths in the digit. That
7 // values are
8 // 1, 2, 3, 5 and 7 = 0 holes,
9 // 0, 4, 6 and 8 = 1 hole,
10 // 9 = 2 holes.
11 // Given a number, process and determine the sum of the number
12 // of holes for all of its digits. For example, the number 879 has
13 // 3 holes.
14 // Complete the program, it must read values as string,
15 // converting the total number of holes to sign.
16 // Constraints
17 // 1 ≤ digits ≤ 100
18 // Input Format (for Custom Testing)
19 // There is one line of text containing an integer representing the
20 // value to process.
21 // Sample Input
22 // 880
23 // Sample Output
24 // 3
25 // Explanation
26 // As the holes count for each digit is 0, 0 and 0. Hence 0 + 0 +
27 // 0 = 0.
28 // Sample Case 1
29 // Sample Input
30 // 1789
31 // Sample Output
32 // 4
33 // Explanation
34 // As the holes count for each digit 1, 0, 8, 9. Hence 0 + 0 + 2 +
35 // 2 = 4.
```

Question 3

Answer

Marked out of 1.00

Flag question

The problem makers have found a new idea for testing and named it as "Market". These expert people have given a task to make a purchase of items at the Market under the constraint various items with different values. Market has come up with a restriction that if we make some categories starting from 0 to 10 the maximum value of the item present in Market, then we can purchase any item easily. He asked the following example to prove his point.

Let's suppose the distribution of an item is 10 then we can make items of 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. So the purchase system ranges from 0 to 10.

Ravi Marthia, being a code reviewer suggested that we could actually determine the number of items required and give following distribution: [0, 1, 2, 3, 4]. According to him any item can be purchased easily ranging from 0 to 10. Everyone was impressed with both of them, Your task is to help Marthia come up with a maximum number of combinations for an arbitrary max given Product.

Input Format

Contains an integer N denoting the maximum price of the item present in Product.

Output Format

Print a single line denoting the maximum number of combinations of items required.

Constraints

$1 \leq n \leq 100$

$1 \leq k \leq 1000$

Note the sample output for formatting

Sample Input 1:

10

Sample Output 1:

4

Sample Input 2:

5

Sample Output 2:

3

Explanation

For test case 1, N=10

According to Marthia [0], [1], [2], [3], [4], [5], [6], [7], [8], [9], [10] results in distribution.

But as per Marthia only [0], [1], [2], [3], [4] items are enough to purchase any item ranging from 0 to 10. Hence minimum is 4. (because combinations available are [0], [1], [2], [3], [4]). Hence answer is 4 and 4.

For test case 2, N=5.

According to Marthia [0], [1], [2], [3], [4], [5] results in distribution.

But as per Marthia only [0], [1], [2], [3] items are enough to purchase any item ranging from 0 to 5. Hence minimum is 3. (because combinations available are [0], [1], [2], [3]). Hence answer is 3 and 3.

Answer: (generate output: 0 %)

```
1 // Problem Statement: Market
2 // The problem makers have found a new idea for testing and
3 // named it as "Market". These expert people have given a task
4 // to make a purchase of items at the Market under the
5 // constraint various items with different values. Market has
6 // come up with a restriction that if we make some categories
7 // starting from 0 to 10 the maximum value of the item present
8 // in Market, then we can purchase any item easily. He asked
9 // the following example to prove his point.
10 // Let's suppose the distribution of an item is 10 then we
11 // can make items of 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. So the
12 // purchase system ranges from 0 to 10.
```

Question 1

Answer

Marked correct

0/1

100% response rate

A set of five numbers generated by an experiment is passed as input to the program. The program must identify the count of number values the number is odd number.

Input Format

The first line will contain five numbers separated by a space.

Boundary Conditions

$1 \leq N \leq 10$

The value of the numbers can be from -1000000000 to 1000000000 .

Output format

The count of numbers after the numbers are odd numbers.

Example Input / Output 1:

Input

2 10 11 20 21 30 31 40 41 50

Output

4

Explanation

The numbers meeting the criteria are 11, 31, 41, 51.

Answer (your code requires 0 %)

```
1 11
2 int main() {
3     int arr[5];
4     for (int i = 0; i < 5; i++) {
5         scanf("%d", &arr[i]);
6         if (arr[i] % 2 != 0) {
7             count++;
8         }
9     }
10    printf("%d", count);
11    return 0;
12 }
```

Question 2

Answer

Marked correct

0/1

100% response rate

Given a number N, return true if and only if N is a rotating number, which satisfies the following condition:

the two whole digits by 180 degrees before new digits when 0, 1, 6, 8, 9 are rotated 180 degrees they become 6, 1, 9, 8 respectively. When 2, 3, 4, 5 and 7 are rotated 180 degrees they become invalid. A rotating number is a number that when rotated 180 degrees becomes a different number with each digit valid.

Example 1

$N = 6$

Input 6

Output true

Explanation

the given number 6, when rotated 180 is a valid number and 6 is 6.

Example 2

$N = 18$

Input 18

Output true

Explanation

the given 18 after rotating 180 86 is a valid number and 86 is 86.

Example 3

$N = 11$

Input 11

Output false

Explanation

the given 11 after rotating 11, 11 is a valid number but the value remains the same, thus 11 is not a rotating number.

Note

- $1 \leq N \leq 10^9$
- After the rotation we can ignore leading zeros, for example if after rotation we have 0018 then this number is considered as 18.

Answer (your code requires 0 %)

```
1 11
2 func isRotating(N) {
3     let str = N.toString();
4     let arr = str.split('');
5     let result = '';
6     for (let i = 0; i < str.length; i++) {
7         let digit = str[i];
8         if (digit === '0' || digit === '1' || digit === '6' || digit === '8' || digit === '9') {
9             result += (digit === '0' ? '0' : digit === '1' ? '1' : digit === '6' ? '9' : digit === '8' ? '3' : digit === '9' ? '6');
10        } else {
11            return false;
12        }
13    }
14    return result !== str;
15 }
```

| Input | Expected | Got |
|-------|----------|-------|
| ✓ 6 | True | True |
| ✓ 18 | True | True |
| ✓ 11 | False | False |

Question 3

Answer

Marked correct

0/1

100% response rate

A collection or labeling of the four powers (terms) in the method. Every four terms arranged in a sequence, defines a value representing item 1 and increasing by 1 for each until all terms have a value associated with them. An item's value is the same as the number of matrices that it has. For example, first term with value 1 has 1 matrix (empty), last term with value 1 has 1 matrix (empty), and increasing in this fashion.

The matrices that is constructed, the four combinations to calculate the maximum total of the operations. However, the matrices that are constructed, a particular item of matrices (matrix) (matrix) number, and the sum is more. The matrices (matrix) four items is the increasing order of their value. Compute the highest total of matrices that can be generated to a point, without the sum matching the given arbitrary number.

Here's an illustration:

Given 4 four terms (power value 1, 2, 3 and 4), and the arbitrary sum being 8 matrix (matrix) increasing from 1, 2, 3 = the sum is 6, which matches the arbitrary sum. Hence, one of the four needs to be stopped. Thus, the best combination is 1 + 2 + 3 = 6.

Given $2 + 2 + 4 = 8$, allows for maximum number of matrices, this is the right answer.

Compute the case for the other cases. It must return an integer that represents the maximum total of matrices, modulo $10^9 + 7$.

It has the following:

- n is an integer that denotes the number of four terms.
- k is an integer that denotes the arbitrary number.

Constraints

- $1 \leq n \leq 10^5$
- $1 \leq k \leq 10^9$

Input format for Custom Testing

The first line contains an integer n , that denotes the number of four terms.

The second line contains an integer k , that denotes the arbitrary number.

Sample Input 1

1

7

Sample Output 1

1

Explanation 1

The following sequence of $n = 1$ four terms is:

- Term 1 has 1 matrix (empty).
- $1 + 2 = 3$, shows that this is the maximum total, and hence, no other terms need to be added.

Sample Input 2

2

1

Sample Output 2

1

Explanation 2

$1 + 1 = 2$, is the best case for matrices with sum.

Answer (your code requires 0 %)

```
1 11
2 int main() {
3     int n, k;
4     cin >> n >> k;
5     long long total = 0;
6     long long mod = 1000000007;
7     for (int i = 1; i <= n; i++) {
8         long long sum = 0;
9         if (sum < k) {
10            sum += i;
11            total++;
12            if (total % mod == 0) {
13                total = total / mod * mod;
14            }
15        }
16    }
17    cout << total;
18    return 0;
19 }
```

| Input | Expected | Got |
|-------|----------|-----|
| ✓ 1 7 | 1 | 1 |
| ✓ 2 1 | 1 | 1 |
| ✓ 2 1 | 1 | 1 |
